Executive Summary

This System Impact Study is the second step of the interconnection process and is based on the PID 287 request for interconnection on Entergy's transmission system at the Lewis Creek 138 kV substation. This report is organized in three sections, namely: Network Resource Interconnection Service (NRIS), Short Circuit/Breaker Rating Analysis, and Stability Study.

Requestor for PID 287 requested NRIS only. The study evaluates the connection of 340 MW to the Entergy Transmission System. The load flow study was performed on the latest available 2017 – 2020 Summer Peak Cases and 2017 – 2020 Winter Peak Cases, using PSS/E and MUST software by Siemens Power Technologies International (Siemens-PTI). The short circuit study was performed on the Entergy system short circuit model using ASPEN software. The proposed in-service date for NRIS is May 1, 2017.

Results of the System Impact Study indicated that under NRIS, the additional generation due to PID 287 generator **does** cause an increase in short circuit current such that it exceeds the fault interrupting capability of the high voltage circuit breakers within the vicinity of the PID 287 plant with priors and without priors. Results also indicated that the system is stable following all simulated three-phase normally cleared and stuck breaker faults. No dynamic voltage problems were noted. Estimated upgrade costs under NRIS with and without priors to replace the identified breakers is \$2,000,000 as listed in the table below.

The estimated cost of interconnection facilities is \$3.5 Million; which covers the cost of the interconnecting to the 138 kV Lewis Creek substation. The estimated costs of the interconnection facilities are planning estimates only. Detailed cost estimates, accelerated costs, and solutions for any identified limiting elements will be provided in the Facilities Study.

Limiting Element	Upgrade Estimate*
Caney Creek - Lewis Creek SES 138kV	\$4,200,000
Ray Braswell - Baxter Wilson 500kV - Supplemental Upgrade	\$91,259
Lewis Creek 138kV Substation	\$2,000,000
Interconnection Facilities	\$3,500,000

Estimated NRIS Project Planning Upgrade Cost

*The costs of the upgrades are planning estimates only. Detailed cost estimates and solutions will be provided in the Facilities Study.

Network Resource Interconnection Service

1. Introduction

A Network Resource Interconnection Services (NRIS) study was requested to serve 340 MW of Entergy network load. The expected in service date for this NRIS generator is May 1, 2017. The tests were performed with only confirmed transmission reservations and existing network generators and with transmission service requests in study mode.

Two tests were performed; a deliverability to generation test and a deliverability to load test. The deliverability to generation (DFAX) test ensures that the addition of this generator will not impair the deliverability of existing network resources and units already designated as NRIS while serving network load. The deliverability to load test determines if the tested generator will reduce the import capability level to certain load pockets (Amite South, WOTAB and Western Region) on the Entergy system. A more detailed description for these two tests is described in Appendix E.

It is understood that the NRIS status provides the Interconnection Customer with the capability to deliver the output of the Generating Facility into the Transmission System. NRIS in and of itself does not convey any right to deliver electricity to any specific customer or Point of Delivery.

2. Short Circuit/Breaker Rating Analysis

2.1 Model Information

The short circuit analysis was performed on the Entergy system short circuit model using ASPEN software. This model includes all generators interconnected to the Entergy system or interconnected to an adjacent system and having an impact on this interconnection request, IPP's with signed IOAs, and approved future transmission projects on the Entergy transmission system.

2.2 Short Circuit Analysis

The method used to determine if any short circuit problems would be caused by the addition of the PID 287 generation is as follows:

Three-phase and single-phase to ground faults were simulated on the Entergy base case short circuit model and the PID 287 generator was then modeled in the base case to generate a revised short circuit model. The base case short circuit results were then compared with the results from the revised model to identify any breakers that were under-rated as a result of additional short circuit contribution from PID 287 generation. Any breakers identified to be upgraded through this comparison are mandatory upgrades.

2.3 Analysis Results

The results of the short circuit analysis indicated that the additional generation due to PID 287 generation caused an increase in short circuit current such that they exceeded the fault interrupting capability of the high voltage circuit breakers within the vicinity of the PID 287 plant **with and without priors**. Priors included are: 221, 231, 238, 240, 244, 247, 250, 256, 260, 261, 266 and 268.

Table 2.1 and Table 2.2 below illustrate the station name, worst case fault level, and the number of breakers that were found to be under-rated at the respective locations as a result of the additional short circuit current due to PID 287 generator with and without priors.

Substation	Breaker	Max Fault w/o PID-287 (amps)	Max Fault with PID-287 (amps)	Interrupting Rating (amps)
	1625-CO	28323.1	36989.5	37000
Lewis Creek	1630-CBO	28323.1	36989.5	37000
138kV	1635-CO	28323.1	36989.5	37000
	1650-CO	28323.1	36989.5	37000
	1660-CO	28323.1	36989.5	37000

Table 2.1: Underrated Breakers Without Priors

Table 2.2: Underrated Breakers With Priors

Substation	Breaker	Max Fault w/o PID-287 (amps)	Max Fault with PID-287(amps)	Interrupting Rating (amps)
	1625-CO	28357.5	37024.5	37000
Lewis Creek	1630-CBO	28357.5	37024.5	37000
138kV	1635-CO	28357.5	37024.5	37000
	1650-CO	28357.5	37024.5	37000
	1660-CO	28357.5	37024.5	37000

2.4 Problem Resolution

Table 2.3 below illustrates the station name, and the cost associated with upgrading the breakers at each station both for mandatory and optional breaker upgrades. The impact on breaker rating due to line upgrades will be evaluated during Facilities Sudy phase.

Table 2.3: Estimated Cost of Breaker Replacement

Substation	Number of Breakers	Estimated cost of Breaker Upgrades (\$)	
Lewis Creek 138kV	5	\$2,000,000	

3. Load Flow Analysis

3.1 Model Information

The models used for this analysis were the 2017 - 2020 summer and winter peak cases developed in 2010.

The following modifications were made to the base cases to reflect the latest information available:

- Non-firm IPPs within the local region of the study generator were turned off and other non-firm IPPs outside the local area were increased to make up the difference.
- Confirmed firm transmission reservations were modeled for the years 2017 -2020.
- Approved transmission reliability upgrades for 2011 2013 were included in the base case. These upgrades can be found at Entergy's OASIS web page <u>http://www.oatioasis.com/EES/EESDocs/Disclaimer.html</u> under approved future projects.

3.2 Contingencies and Monitored Elements

Single contingency analyses on Entergy's transmission facilities (including tie lines) 115 kV and above were considered. All transmission facilities on Entergy transmission system above 100 kV were monitored.

Power Factor Consideration / Criteria

Entergy, consistent with the FERC Large Generator Interconnection Procedures (LGIP) requires the customer to be capable of supplying at least 0.33 MVAR (*i.e.*, 0.95 lagging power factor) and absorbing at least 0.33 MVAR (*i.e.*, 0.95 leading power factor) for every MW of power injected into the grid. In the event that, under normal operating conditions, the customer facility does not meet the prescribed power factor requirements at the point of interconnection, the customer shall take necessary steps, such as the installation of reactive power compensating devices, to achieve the desired power factor.

The customer meets the criteria as stated above.

3.3 Generation used for the transfer

The Customer's generators were used as the source for the deliverability to generation test.

3.4 Analysis Results

3.4.1 Deliverability to Generation (DFAX) Test

The deliverability to generation (DFAX) test ensures that the addition of this generator will not impair the deliverability of existing network resources and units already designated as NRIS while serving network load. A more detailed description for these two tests is described in Appendix E.

3.4.2 Constraints

Study Case	Study Case with Priors
Caney Creek - Lewis Creek SES 138kV	Caney Creek - Lewis Creek SES 138kV
Ray Braswell - Baxter Wilson 500kV -	Ray Braswell - Baxter Wilson 500kV -
Supplemental Upgrade	Supplemental Upgrade

3.4.3 DFAX Study Case Results

Year	Limiting Element	Contingency Element	ATC (MW)
5/1/2017	Ray Braswell - Baxter Wilson 500kV -		
_	Supplemental Upgrade	Franklin - Grand Gulf 500kV	-448
5/1/2020	Caney Creek - Lewis Creek SES 138kV	Alden - Lewis Creek SES 138kV	296

3.4.4 DFAX Study with Priors Case Results

Year	Limiting Element	Contingency Element	ATC (MW)
5/1/2017	Ray Braswell - Baxter Wilson 500kV -		
_	Supplemental Upgrade	Franklin - Grand Gulf 500kV	-1127
5/1/2020	Caney Creek - Lewis Creek SES 138kV	Alden - Lewis Creek SES 138kV	298

3.4.5 Deliverability to Load Test

The deliverability to load test determines if the tested generator will reduce the import capability level to certain load pockets (Amite South, WOTAB and Western Region) on the Entergy system. A more detailed description for these two tests is described in Appendix E.

- A. Amite South: Passed
- B. WOTAB: Passed
- C. Western Region: Passed

4. Required Upgrades for NRIS

4.1 Preliminary Estimates of Direct Assignment of Facilities and Network Upgrades

Limiting Element	Upgrade Estimate*
Caney Creek - Lewis Creek SES 138kV	\$4,200,000
Ray Braswell - Baxter Wilson 500kV -	
Supplemental Upgrade	\$91,259
Lewis Creek 138kV Substation	\$2,000,000

*The costs of the upgrades are planning estimates only. Detailed cost estimates, accelerated costs and solutions for the limiting elements will be provided in the Facilities Study.

5. Interconnection Facilities

The Interconnection Customer's designated Point of Interconnection (POI) is the Lewis Creek 138 kV substation. The estimated cost of interconnection facilities is \$3.5 Million. This cost is based on parametric estimating techniques for a "typical" site. Cost may significantly change based on specific project parameters that are not known at this time. Costs specific to this interconnection will be developed during the Facilities Study. The interconnection customer is responsible for constructing all facilities needed to deliver generation to the POI.

Stability Study

6. Executive Summary

Southwest Power Pool (SPP) requested ABB Power Systems Consulting to perform a stability analysis for PID 287, which is a 340 MW generating. The proposed project is a Combined Cycle Plant and is an interconnection request for the expansion of the existing Lewis Creek facility located at Lewis Creek 138 kV substation in Montgomery County, Texas in the Entergy service territory.

The objective of this study is to determine if the interconnection of PID 287 will cause any adverse stability impacts on the Entergy system. The study was performed on 2017 Summer Peak case, provided by SPP/Entergy.

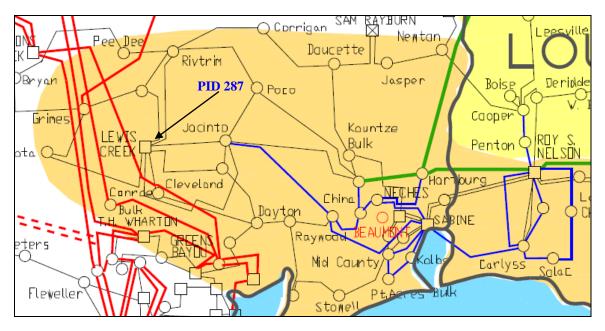

Figure 6.1: PID 287 Point of Interconnection

7. Final conclusions

Based on the results of stability analysis, it can be concluded that the proposed PID 287 project does not adversely impact the stability of the Entergy System in the local area. The system was stable following all simulated normally-cleared three-phase faults and single-line-to-ground (SLG) stuck-breaker faults. No angular instabilities were observed. Also, no voltage criteria violations were observed following the simulated faults.

8. Project Description

The proposed PID 287 project will be located in Montgomery County, Texas in the Entergy service territory. Power will be generated using a Combustion Turbine Generator (CTG) and a Steam Turbine Generator (STG) operating in a one-on-one configuration. The following list summarizes the major project parameters:

Interconnection: Lewis Creek 138 kV sub-station

CTG Data:

General:

- Gross MW: 192 MW
- Auxiliary Power Consumption: 10 MW

Generator Step-up Transformer (GSU):

- MVA: 236.2 MVA
- High voltage: 138 kV
- Low voltage: 18 kV
- Z: 8.75%, X/R = 30

Generator:

- Manufacturer: GE
- MVA: 229 MVA
- Rayed voltage: 18 kV
- Power Factor: 0.85
- Model: GENROU
- AVR: ESST4B
- Governor: GGOV1

STG Data:

General:

- Gross MW: 158 MW
- Auxiliary Power Consumption: All BOP Load is attributed to the CTG Auxiliary Transformer for the purpose of this request.

Generator Step-up Transformer (GSU):

- MVA: 183.4 MVA
- High voltage: 138 kV
- Low voltage: 18 kV
- Z: 8.75%, X/R = 30

Generator:

- Manufacturer: GE
- MVA: 180 MVA
- Rayed voltage: 18 kV
- Power Factor: 0.85
- Model: GENROU
- AVR: ESST4B
- Governor: TGOV1

9. Stability Analysis

9.1 Stability Analysis Methodology

The goal of the stability analysis is to verify that the response to dynamic events (e.g. faults) is acceptable (i.e. no out-of-step condition, acceptable voltage recovery, postdisturbance, damped oscillations) with the proposed PID 287 in service

Stability analysis was performed using Siemens-PTI's PSS/E[™] dynamics program V30.3.3. Three-phase and SLG with stuck breaker faults were simulated for the specified duration and synchronous machine rotor angles were monitored to check whether synchronism is maintained following fault removal. In addition, voltages were monitored on selected buses in the study area to check for voltage criteria violations (see below).

The following transient voltage criteria were used:

- Three-phase fault or single-line-ground (SLG) fault with normal clearing resulting in the loss of a single component (generator, transmission circuit or transformer) or a loss of a single component without fault:
 - Not to exceed 20% for more than 20 cycles at any bus
 - Not to exceed 25% at any load bus
 - Not to exceed 30% at any non-load bus
- Three-phase faults with normal clearing resulting in the loss of two (2) or more components (generator, transmission circuit or transformer), and SLG fault with delayed clearing resulting in the loss of one (1) or more components:
 - Not to exceed 20% for more than 40 cycles at any bus
 - Not to exceed 30% at any bus

The duration of the transient voltage dip excludes the duration of the fault. The transient voltage dip criteria will not be applied to three-phase faults followed by stuck-breaker conditions unless the determined impact is extremely widespread.

The voltages at all local buses were monitored during each of the fault cases as appropriate.

9.2 Study Model Development

The PID 287 generation plant is modeled as a CTG of 192 MW and a STG of 158 MW. The voltage at the each generator terminal is 18 kV and is connected to the point of interconnection of PID 287 via two (2) 18/138 kV generator step-up transformers (one on each unit). Plant auxiliary load was modeled at 10 MW with an assumed power factor of 0.85 lag. Data for the proposed PID 287 project is included in Appendix A.

The study model consists of a power flow case and a dynamics database, developed as follows:

9.2.1 Power Flow Case

A powerflow case "EN17S10_U3_final_CP_V30_unconv.sav" representing 2017 Summer Peak conditions was provided by SPP/ Entergy.

A post-project power flow case with PID 287 was established and named as 'EN17S10_U3_final_CP_V30_unconv-PID287.sav'.

Figure 9.1 and Figure 9.2 show the PSS/E one-line diagrams for the local area without and with the PID 287 project, respectively.

9.2.2 Stability Database

A basecase stability database was provided by SPP/Entergy in a PSSE *.dyr and *.snp file format (red16S_newnum.dyr; drift.snp).

The stability data for PID 287 was appended to the above mentioned stability database to come up with a post-project stability database.

The data provided for the Interconnection Request for PID 287 is included in Appendix A. The PSS/E power flow and stability data for PID 287 are included in Appendix B.

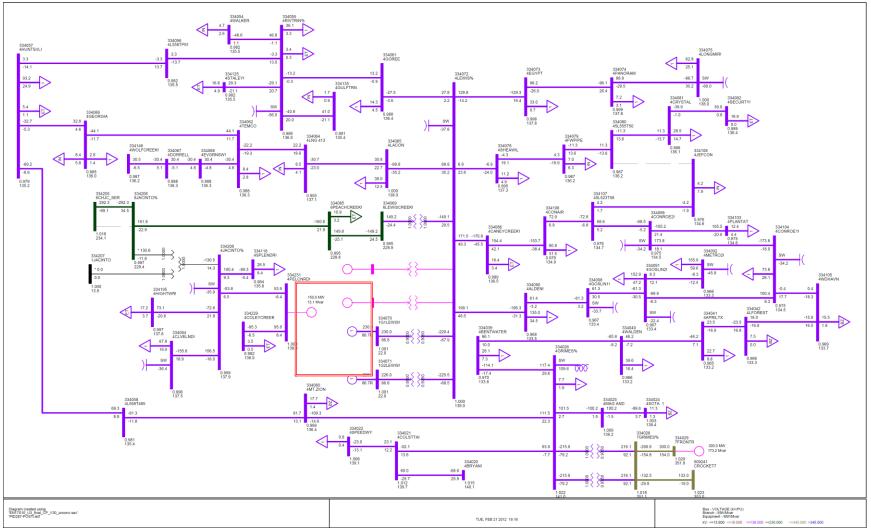

Figure 9.1: 2017 Summer Peak Flows and Voltages without PID 287

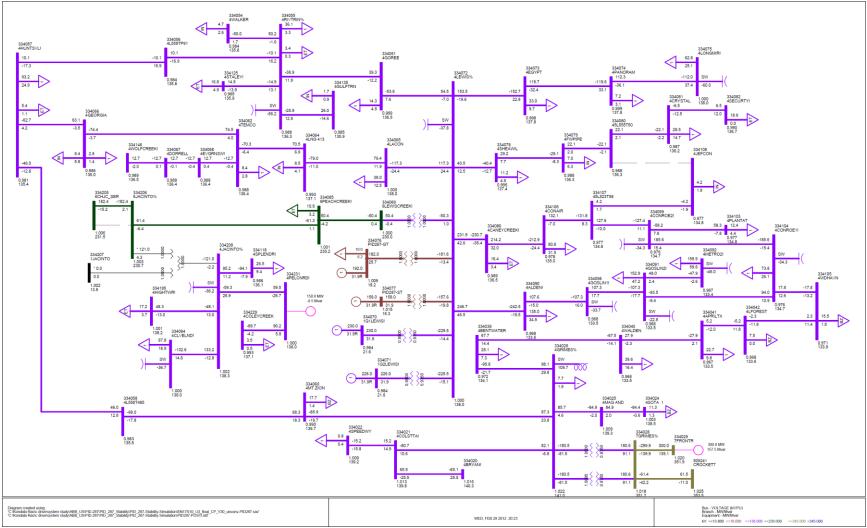

Figure 9.2: 2017 Summer Peak Flows and Voltages with PID 287

9.3 Transient Stability Analysis

Stability simulations were run to examine the transient behavior of the PID 287 generation and its impact on the Entergy system. Stability analysis was performed using the following procedure. First, three-phase faults with normal clearing were simulated. Next, SLG stuck-breaker faults were simulated. The fault clearing times used for the simulations are given in Table 9.1 below.

Faulted bus kV level	Normal Clearing	Delayed Clearing
138	6 cycles	6+13 cycles
230	6 cycles	6+9 cycles
345	5 cycles	5+9 cycles

Table 9.1: Fault Clearing Times

All line trips are assumed to be permanent (i.e., no high speed re-closure).

Table 9.2 and Table 9.3 list the fault cases that were simulated in this study for threephase normal clearing and SLG with stuck breaker faults respectively. Twenty-three (23) three-phase normally cleared and eighteen (18) SLG stuck-breaker faults were simulated. Figure 9.3 through Figure 9.8 show the breaker layout diagrams for substations where faults were simulated.

For all cases analyzed, the initial disturbance was applied at t = 0.1 seconds.

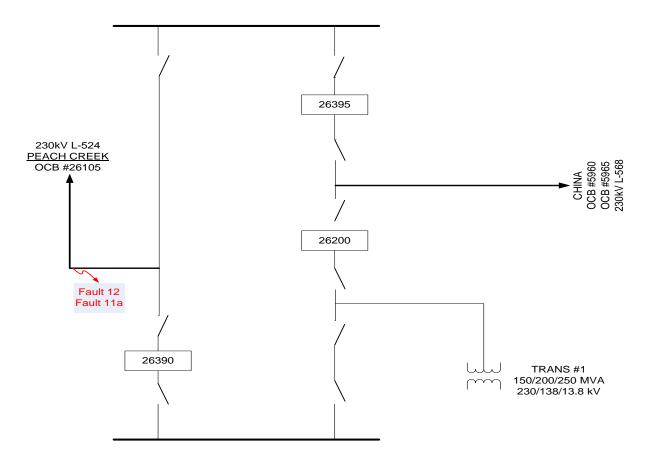

Figure 9.5: Jacinto 230 kV Substation

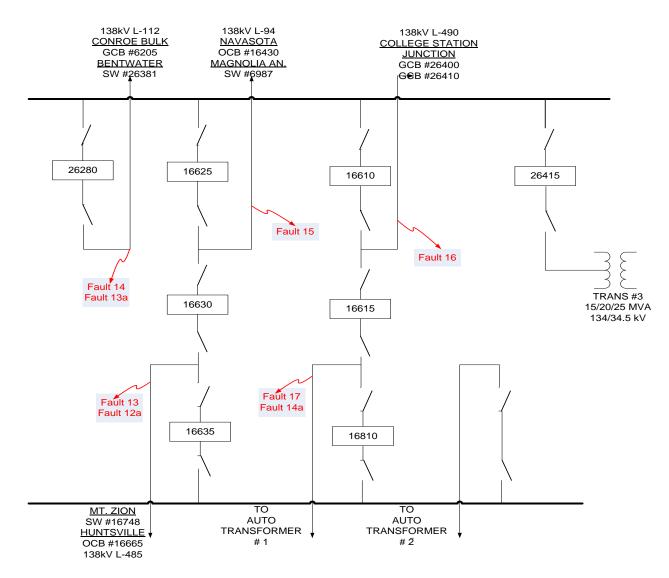

Figure 9.6: Grimes 138 kV Substation

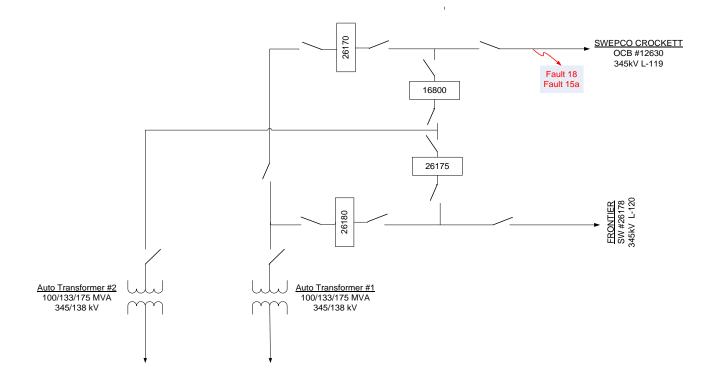

Figure 9.7: Grimes 345 kV Substation

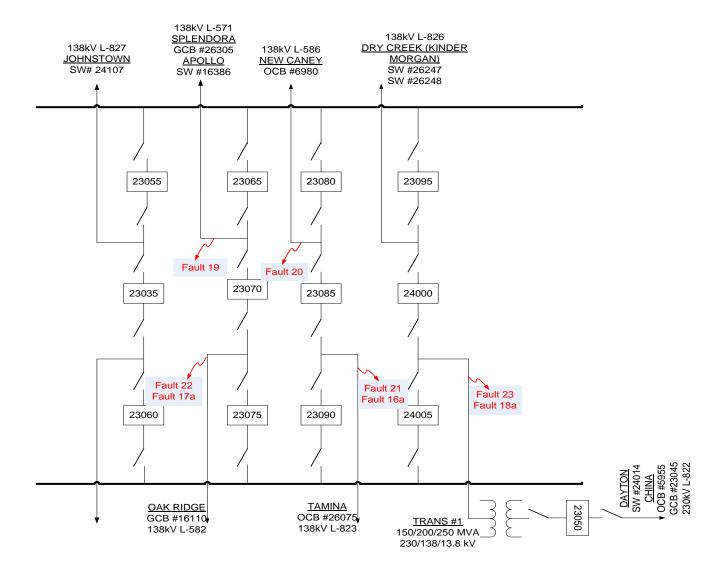

Figure 9.8: Porter 138 kV Substation

The system was found to be STABLE following all the simulated faults. Table 9.4 shows the simulation results for the three-phase normally cleared and stuck-breaker faults and the plots for the stability simulations are included in Appendix C.

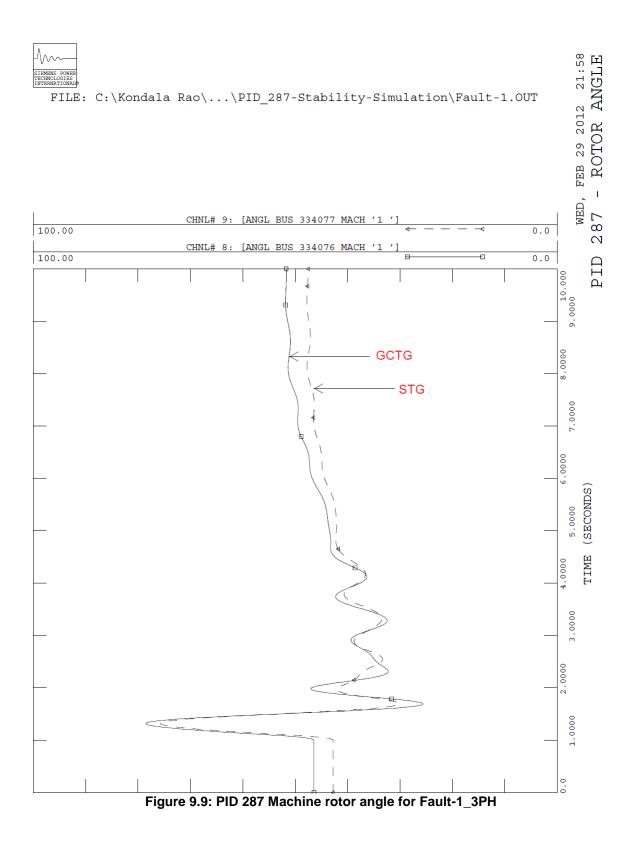

Figure 9.9 and Figure 9.10 shows the CTG and STG quantities for Fault 1, which is a three-phase fault at the PID 287 POI bus on the Longmire 138 kV line.

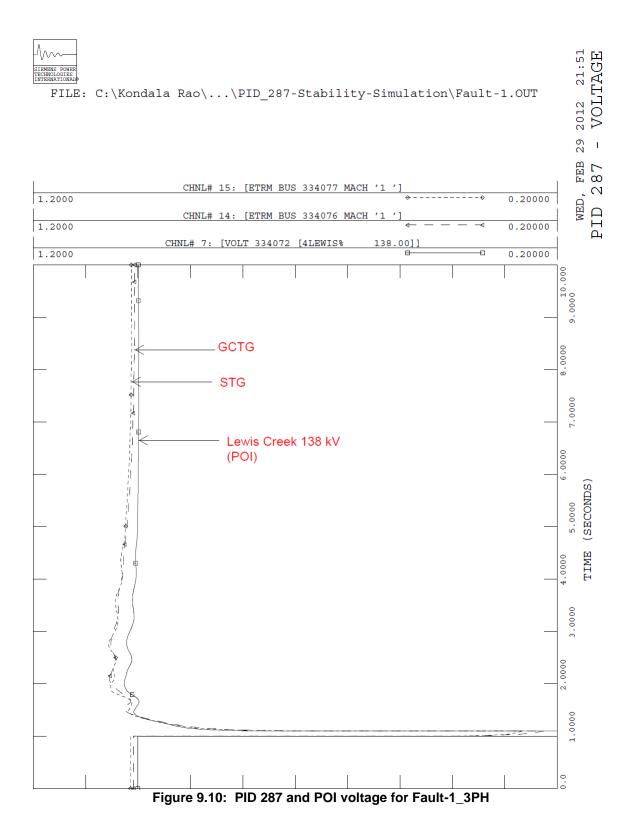

9.3.1 Transient Voltage Recovery

No voltage criteria violations were observed following the simulated faults.

The voltages at all buses in the Entergy system in the vicinity of the project were monitored during each of the fault cases. No voltage criteria violations were observed following normally-cleared three-phase faults.

As there are no specific voltage dip criteria for SLG stuck-breaker faults, the results of these faults were compared with the most stringent voltage dip criteria of - not to exceed 20 % for more than 20 cycles. After comparison against the voltage-criteria, no faults were found to be in violation.

APPENDIX A: Data Provided by Customer

APPENDIX 1 to LGIP INTERCONNECTION REQUEST FOR A LARGE GENERATING FACILITY

- 1. The undersigned Interconnection Customer submits this request to interconnect its Large Generating Facility with Transmission Provider's Transmission System pursuant to a Tariff.
- 2. This Interconnection Request is for (check one):
 - X A proposed new Large Generating Facility.
 - ____ An increase in the generating capacity or a <u>Material Modification</u> of an existing Generating Facility.
- 3. The type of interconnection service requested (check one): Energy Resource Interconnection Service X Network Resource Interconnection Service
- 4. Check here only if Interconnection Customer requesting Network Resource Interconnection Service also seeks to have its Generating Facility studied for Energy Resource Interconnection Service
- 5. Interconnection Customer provides the following information:
 - Address or location or the proposed new Large Generating Facility site (to the extent known) or, in the case of an existing Generating Facility, the name and specific location of the existing Generating Facility; Lewis Creek 138kV bus, Montgomery County, Texas
 - b. Summer and Winter electrical output Maximum summer at <u>36°C (163 MW + 157 MW- 10 MW= **310 MW**)</u> and winter at <u>-1°C (192 MW + 158 MW -10 MW = **340 MW**)</u> degrees C megawatt electrical output of the new Large Generating Facility or the amount of megawatt increase in the generating capacity of an existing Generating Facility;`
 - c. General description of the equipment configuration; <u>A combustion turbine unit tied to the Lewis Creek 138kV station trough a 138/18kV auto transformer and a steam turbine unit tied to the Lewis Creek 138kV station through a 138/18kV autotransformer. Please see one-line for electrical connection to the grid.</u>

- Commercial Operation Date (Day, Month, and Year); <u>May 1, 2017</u>
- e. Name, address, telephone number, and e-mail address of Interconnection Customer's contact person;
- f. Approximate location of the proposed Point of Interconnection (optional); and
- g. Interconnection Customer Data (set forth in Attachment A)
- 6. Applicable deposit amount as specified in the LGIP.
- Evidence of Site Control as specified in the LGIP (check one)
 X Is attached to this Interconnection Request
 Will be provided at a later date in accordance with this LGIP

This Interconnection Request shall be submitted to the representative indicated below:

[To be completed by Transmission Provider]

- 9. Representative of Interconnection Customer to contact:
- 10. This Interconnection Request is submitted by:

Name of Interconnection Customer:

By (signature):

Name (type or print):

EXCITATION SYSTEM DATA

Identify appropriate IEEE model block diagram of excitation system and power system stabilizer (PSS) for computer representation in power system stability simulations and the corresponding excitation system and PSS constants for use in the model.

Excitation system model is ESST4B. See attached for constants. PSS system model is PSS2B (Similar to PSS2A). See attached for constants.

GOVERNOR SYSTEM DATA

Identify appropriate IEEE model block diagram of governor system for computer representation in power system stability simulations and the corresponding governor system constants for use in the model.

Governor model is GGOV1. See attached for constants.

WIND GENERATORS

Number of generators to be interconnected pursuant to this Interconnection Request:

Elevation: _____ Single Phase _____ Three Phase

Inverter manufacturer, model name, number, and version:

List of adjustable setpoints for the protective equipment or software:

Note: A completed General Electric Company Power Systems Load Flow (PSLF) data sheet or other compatible formats, such as IEEE and PTI power flow models, must be supplied with the Interconnection Request. If other data sheets are more appropriate to the proposed device, then they shall be provided and discussed at Scoping Meeting.

EXCITATION SYSTEM DATA

Identify appropriate IEEE model block diagram of excitation system and power system stabilizer (PSS) for computer representation in power system stability simulations and the corresponding excitation system and PSS constants for use in the model.

Excitation system model is ESST4B. See attached for constants. PSS system model is PSS2A. See attached for constants.

GOVERNOR SYSTEM DATA

Identify appropriate IEEE model block diagram of governor system for computer representation in power system stability simulations and the corresponding governor system constants for use in the model.

Governor model is TGOV1. See attached for constants.

WIND GENERATORS

Number of generators to be interconnected pursuant to this Interconnection Request:

Elevation: _____ Single Phase _____ Three Phase

Inverter manufacturer, model name, number, and version:

List of adjustable setpoints for the protective equipment or software:

Note: A completed General Electric Company Power Systems Load Flow (PSLF) data sheet or other compatible formats, such as IEEE and PTI power flow models, must be supplied with the Interconnection Request. If other data sheets are more appropriate to the proposed device, then they shall be provided and discussed at Scoping Meeting.

APPENDIX E: Deliverability Tests for Network Resource Interconnection Service Resources

Overview

Entergy will develop a two-part deliverability test for customers (Interconnection Customers or Network Customers) seeking to qualify a Generator as an NRIS resource: 1) a test of deliverability "from generation", that is out of the Generator to the aggregate load connected to the Entergy Transmission system; and 2) a test of deliverability "to load" associated with subzones. This test will identify upgrades that are required to make the resource deliverable and to maintain that deliverability for a five year period.

The "From Generation" Test for Deliverability

In order for a Generator to be considered deliverable, it must be able to run at its maximum rated output without impairing the capability of the aggregate of previously qualified generating resources (whether qualified at the NRIS or NITS level) in the local area to support load on the system, taking into account potentially constrained transmission elements common to the Generator under test and other adjacent qualified resources. For purposes of this test, the resources displaced in order to determine if the Generator under test can run at maximum rated output should be resources located outside of the local area and having insignificant impact on the results. Existing Long-term Firm PTP Service commitments will also be maintained in this study procedure.

The "To Load" Test for Deliverability

The Generator under test running at its rated output cannot introduce flows on the system that would adversely affect the ability of the transmission system to serve load reliably in import-constrained sub-zones. Existing Long-term Firm PTP Service commitments will also be maintained in this study procedure.

Required Upgrades

Entergy will determine what upgrades, if any, will be required for an NRIS applicant to meet deliverability requirements pursuant to Appendix A.

Description of Deliverability Test

Each NRIS resource will be tested for deliverability at peak load conditions, and in such a manner that the resources it displaces in the test are ones that could continue to contribute to the resource adequacy of the control area in addition to the studied resources. The study will also determine if a unit applying for NRIS service impairs the reliability of load on the system by reducing the capability of the transmission system to deliver energy to load located in import-constrained sub-zones on the grid. Through the study, any transmission upgrades necessary for the unit to meet these tests will be identified.

Deliverability Test Procedure

The deliverability test for qualifying a generating unit as a NRIS resource is intended to ensure that 1) the generating resource being studied contributes to the reliability of the system as a whole by being able to, in conjunction with all other Network Resources on the system, deliver energy to the aggregate load on the transmission system, and 2) collectively all load on the system can still be reliably served with the inclusion of the generating resource being studied.

The tests are conducted for "peak" conditions (both a summer peak and a winter peak) for each year of the 5-year planning horizon commencing in the first year the new unit is scheduled to commence operations.

Deliverability of Generation

The intent of this test is to determine the deliverability of a NRIS resource to the aggregate load on the system. It is assumed in this test that all units previously qualified

as NRIS and NITS resources are deliverable. In evaluating the incremental deliverability of a new resource, a test case is established. In the test case, all existing NRIS and NITS resources are dispatched at an expected level of generation (as modified by the DFAX list units as discussed below). Peak load withdrawals are also modeled as well as net imports and exports. The output from generating resources is then adjusted so as to "balance" overall load and generation. This sets the baseline for the test case in terms of total system injections and withdrawals.

Incremental to this test case, injections from the proposed new generation facility are then included, with reductions in other generation located outside of the local area made to maintain system balance.

Generator deliverability is then tested for each transmission facility. There are two steps to identify the transmission facilities to be studied and the pattern of generation on the system:

- 1) Identify the transmission facilities for which the generator being studied has a 3% or greater distribution factor.
- For each such transmission facility, list all existing qualified NRIS and NITS resources having a 3% or greater distribution factor on that facility. This list of units is called the Distribution Factor or DFAX list.

For each transmission facility, the units on the DFAX list with the greatest impact are modeled as operating at 100% of their rated output in the DC load flow until, working down the DFAX list, a 20% probability of all units being available at full output is reached (e.g. for 15 generators with a Forced Outage Rate of 10%, the probability of all 15 being available at 100% of their rated output is 20.6%). Other NRIS and NITS resources on the system are modeled at a level sufficient to serve load and net interchange. From this new baseline, if the addition of the generator being considered (coupled with the matching generation reduction on the system) results in overloads on a particular transmission facility being examined, then it is not "deliverable" under the test.

Deliverability to Load

The Entergy transmission system is divided into a number of import constrained subzones for which the import capability and reliability criteria will be examined for the purposes of testing a new NRIS resource. These sub-zones can be characterized as being areas on the Entergy transmission system for which transmission limitations restrict the import of energy necessary to supply load located in the sub-zone.

The transmission limitations will be defined by contingencies and transmission constraints on the system that are known to limit operations in each area, and the subzones will be defined by the generation and load busses that are impacted by the contingent transmission lines. These sub-zones may change over time as the topology of the transmission system changes or load grows in particular areas.

An acceptable level of import capability for each sub-zone will have been determined by Entergy Transmission based on their experience and modeling of joint transmission and generating unit contingencies. Typically the acceptable level of transmission import capacity into the sub-zones will be that which is limited by first-contingency conditions on the transmission system when generating units within the sub-region are experiencing an abnormal level of outages and peak loads.

The "deliverability to load" test compares the available import capability to each sub-zone that is required for the maintaining of reliable service to load within the sub-zone both with and without the new NRIS resource operating at 100% of its rated output. If the new NRIS resource does not reduce the sub-zone import capability so as to reduce the reliability of load within the sub-zone to an unacceptable level, then the deliverability to load test for the unit is satisfied. This test is conducted for a 5-year planning cycle. When the new NRIS resource fails the test, then transmission upgrades will be identified

that would allow the NRIS unit to operate without degrading the sub-zone reliability to below an acceptable level.

Other Modeling Assumptions

Modeling of Other Resources

Generating units outside the control of Entergy (including the network resources of others, and generating units in adjacent control areas) shall be modeled assuming "worst case" operation of the units – that is, a pattern of dispatch that reduces the sub-zone import capability, or impact the common limiting flowgates on the system to the greatest extent for the "from generation" deliverability test.

Must-run Units

Must-run units in the control area will be modeled as committed and operating at a level consistent with the must-run operating guidelines for the unit.

Base-line Transmission Model

The base-line transmission system will include all transmission upgrades approved and committed to by Entergy Transmission over the 5-year planning horizon. Transmission line ratings will be net of TRM and current CBM assumptions will be maintained.
